RE: Baseline Health Risk Assessment Report for OU-1 Soil Gas and Groundwater
Nevada Environmental Response Trust
Henderson, Nevada

Dear Dr. Dong:

The Nevada Environmental Response Trust (NERT) is pleased to present the Baseline Health Risk Assessment Report for OU-1 Soil Gas and Groundwater, Revision 1 for Nevada Division of Environmental Protection (NDEP) review. This report has been revised in accordance with NDEP's comments dated March 9, 2022, NERT's response dated June 24, 2022, and NDEP's clarifying comments on November 3, 2022. Additionally, the report was further updated to reflect NDEP's June 2023 updates to the Basic Comparison Levels and other modifications as required due to the passage of time. As requested, NERT has also prepared an annotated response to comments summarizing the revisions addressing NDEP's comments.

If you have any questions or concerns regarding this matter, feel to contact me at (702) 960-4309 or at steve.clough@nert-trust.com.

Office of the Nevada Environmental Response Trust

<p style="text-align: center;">Initial NDEP Comments (3/9/22)</p>	<p style="text-align: center;">NERT's First Response (6/24/22)</p>	<p style="text-align: center;">NDEP Comment on NERT's First Response (11/3/22)</p>	<p style="text-align: center;">NERT's Second Response (11/3/23)</p>
<p><u>#1 Executive Summary, p. ES-2. 1st full paragraph, last sentence.</u></p> <p>Please clarify by expanding the sentence. As written, this sentence leaves the reader hanging.</p>	<p>The sentence cited in the comment states "It should be noted that the cancer risk and noncancer hazard estimated in this BHRA do not represent absolute estimates in OU-1, since generic and conservative assumptions were used when values specific to the Operations Area were not available, which are likely to overestimate actual exposures and calculated risks."</p> <p>To clarify, we can add a sentence after the cited text to Revision 1 of the Baseline Health Risk Assessment Report for OU-1 Soil Gas and Groundwater ("Revised Report") as follows:</p> <p>"The actual health risks associated with exposure through the vapor intrusion pathway from soil gas and shallow groundwater within the Operations Area of OU-1 for the on-Site workers are expected to be lower than the risk estimates reported in this BHRA".</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, the following sentence, slightly revised from the June 24, 2022 response, was added to the end of the first full paragraph on page ES-3, "Therefore, the actual health risks associated with exposure through the vapor intrusion pathway from soil gas and shallow groundwater within the Operations Area of OU-1 for the on-Site workers are expected to be lower than the risk estimates reported in this BHRA."</p>
<p><u>#2 Section 4.2.3 and associated Figures.</u></p> <p>The temporal bar plots in general show little data. What they mostly show is a comparison of two wells in the OSSM-derived plume area compared to one well in an area of much lower concentration in the NERT-derived plume area.</p> <p>Please include more soil gas wells for temporal description of activity over time on the east side of OU-1 or explain why these wells were left out (such as those included later in the correlation plots, RISG-23, and RISG-82). It might be that even at shallow depths there were no samples from the 2008 Phase B investigation, but please make this or other reasoning more explicit in this section. It may also be helpful to include a comparable Table 4-3 for soil gas locations.</p> <p>Please also explain why the temporal trends at RISG-14 might be meaningful with respect to the potential source of chloroform on the east side of OU-1.</p>	<p>Soil gas data is available from 2008 (Phase B investigation completed by Tronox) and 2019 (Phase 2 and Phase 3 RI). The 2008 soil gas samples were collected at 5 feet below ground surface (ft bgs). For the temporal trend analysis, Ramboll evaluated all three 2008 locations that were within 50 feet from a 2019 sampling location and located within the chlorinated volatile organic compounds (VOCs) groundwater plumes.</p> <p>In order to include more soil gas locations in the temporal trend analysis of the Revised Report, Ramboll can change the inclusion criteria and include any 2008 locations that are located within approximately 100 feet of a 2019 sampling location. This will result in eight additional soil gas locations in the temporal trend analysis, including RISG-82 on the east side of OU-1. The impact of increasing the distance between the 2008 and 2019 soil gas locations will be discussed in the Uncertainty Analysis of the Revised Report.</p> <p>In addition, a new table summarizing soil gas sample locations can be added to the Revised Report that provides information comparable to existing Table 4-3 'Shallow Groundwater Wells Included in the BHRA Data Set'.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, as requested, a table (Table 4-3a – former 4-3a changed to 4-3b) was added to summarize the soil gas samples included in the BHRA.</p> <p>Soil gas samples with a depth of 5 ft bgs taken in the 2008 and 2019/2020 sampling events within approximately 100 feet of one another were grouped for evaluation. The grouped samples are presented in Table 4-3c. Figure 4-19 shows a temporal distribution of the samples taken in 2008 and 2019/2020.</p> <p>The following text was added to address the comment raised regarding sample location RISG-14, "These sample points are in the vicinity of other soil gas locations within the Unit 4 Building footprint, which do not have results available from nearby Phase B locations or at a depth of 5 feet bgs. The chloroform results at RISG-14, are similar in magnitude to the results from the locations within the Unit 4 Building footprint. Thus, the results from RISG-14 (and Phase B location SG69) can be used to evaluate how the source of chloroform at the Unit 4 Building is changing over time. The chloroform concentrations at RISG-14/SG69 were significantly lower in 2019 than in 2008,</p>

Initial NDEP Comments (3/9/22)	NERT's First Response (6/24/22)	NDEP Comment on NERT's First Response (11/3/22)	NERT's Second Response (11/3/23)
	<p>With respect to the comment related to RISG-14, the temporal trend at this location is meaningful because RISG-14 is within the chloroform plume at the Unit 4 Building, a source of chloroform in soil gas. While there are other soil gas locations within the Unit 4 Building footprint, these other locations do not have results available from nearby Phase B locations that could be used to evaluate the temporal trend between 2008 and 2019.</p> <p>The chloroform results at RISG-14 are similar in magnitude to the results from the locations within the Unit 4 Building footing. Thus, the results from RISG-14 (and Phase B location SG69) can be used to evaluate how the source of chloroform at the Unit 4 Building is changing over time. The chloroform concentrations at RISG-14/SG69 were significantly lower in 2019 than in 2008 indicating that there is a decreasing temporal concentration trend at the Unit 4 Building. The text in Section 4.2.3 of the Revised Report can be modified to provide additional clarification of why the temporal trends at RISG-14 might be meaningful with respect to chloroform contamination associated with former operations at the Unit 4 Building.</p>		<p>indicating that there is a decreasing temporal concentration trend at the Unit 4 Building.”</p>
<p>#3 Section 4.2.3, Shallow Groundwater.</p> <p>First, it was helpful to see both figures 4-12a (at the same scale as figure 4-11) and 4-12b (at a scale relevant to only the data presented).</p> <p>However, it is unclear why samples taken from wells upgradient of the former Beta Ditch would be excluded. It is also not clear why temporal trends for wells with concentrations over 1,000 µg/L are the only ones of interest. Chloroform exists on OU-1 upgradient of the former Beta Ditch and east, and possibly separated from the groundwater plume originating from OSSM (Figure 3-2) at levels lower than 1,000 µg/L but above the screening level of 70 µg/L. These concentration levels rule out looking temporally at any wells also used in section 4.2.4.</p>	<p>The purpose of this groundwater temporal trend evaluation was to analyze the temporal trend of chloroform in the area with the highest chloroform concentrations and potential health risks. Thus, the groundwater temporal analysis focused on locations in the area with chloroform concentrations over 1,000 µg/L within the chlorinated VOC groundwater plumes in OU-1.</p> <p>In order to evaluate temporal trends in areas with lower chloroform concentrations, additional locations can be integrated into Section 4.2.3 of the Revised Report including locations upgradient of the former Beta Ditch and within the chlorinated VOC groundwater plumes. This temporal trend analysis would focus on groundwater locations with chloroform concentrations over 150 µg/L, which is the minimum risk-based target concentration (RBTC) for chloroform among all scenarios. It is anticipated that approximately 20 wells could be added to this analysis.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, as described in the 'Shallow Groundwater' portion of Section 4.2.3, wells with at least one measured concentration greater than 150 µg/L were included in the temporal evaluation. Results for wells within the OSSM plume are presented in Figure 4-20 (which replaces former Figure 4-11), and results within the BHRA Area are presented in Figures 4-21a and 4-21b (which replace former Figures 4-12a and 4-12b).</p> <p>Spatial concentration bubble plots were also prepared for chloroform, carbon tetrachloride, and 1,4-dichlorobenzene as presented in Figures 4-10 through 4-18.</p>

Initial NDEP Comments (3/9/22)	NERT's First Response (6/24/22)	NDEP Comment on NERT's First Response (11/3/22)	NERT's Second Response (11/3/23)
<p>Please make it clearer why temporal trends were of interest for only these concentration levels. It removes a large portion of wells on OU-1 unrelated to the OSSM plume, which makes up a small spatial portion of OU-1.</p> <p>Also, it is not clear why some spatial contouring has not been done to support any arguments made. These could include spatio-temporal plots that would allow more data to be brought into the analysis.</p>	<p>In addition, spatial plots with a continuous concentration scale consistent with recommendations in Neptune's memo on NERT spatial plots dated February 18, 2022 will be prepared and included in the Revised Report for the chemicals that were detected at a concentration greater than 10% of the lowest RBTC for vapor intrusion.</p>		
<p><u>#4 Section 4.2.4.</u></p> <p>The correlation analysis is not compelling. It is driven by a couple of high concentrations. Have any diagnostics of the regression analysis been performed to confirm the correlation analysis? It appears that the correlation analysis is driven by one or two influential points.</p>	<p>It is the opinion of Ramboll that the correlation analysis plots presented in Figures 4-13 and 4-14 clearly show that: 1) higher chloroform concentrations in soil gas are associated with higher chloroform concentrations in shallow groundwater, and 2) the correlations are driven by one or two high concentrations. Accordingly, we do not believe there is a need to present regression diagnostics since this is already evident in the presentation of the results. Thus, while acknowledging the limited number of samples included in the correlation analysis, we believe the data is sufficient for this purpose and are generally consistent with the CSM which concluded that the chloroform in soil gas is from groundwater within the groundwater VOC plumes. Section 4.2.4 of the Revised Report can be modified to justify the conclusion and acknowledge the uncertainty in the correlation analysis.</p>	<p>As noted in the response, the correlations are driven by one or two high concentrations. This violates the basic assumptions of a linear regression analysis – that is, that the residuals should be normally distributed around zero. This is clearly not the case here. Consequently, the regression analysis cannot be relied upon. Otherwise, statements could be made that the two highest concentrations in GW are from the same locations as the two highest concentrations in soil gas – for the other 4 data points, there is no correlation. Are there any other data that can be brought to bear on this? Even in the log-based scatter plot, the low 4 values show no relationship, and the (weaker) relationship indicated (weaker than non-log) is still driven by the 2 high values. Perhaps a more appropriate argument should be one that simply addresses the very high concentrations are collocated and the 4 lower concentrations are collocated. Not much more than that is supported by the data and the subsequent statistical analysis.</p>	<p>The Revised Report has been updated to reflect NDEP's clarifying comments. Specifically, additional correlation analyses were performed on the co-located soil gas and groundwater sample dataset, including how soil gas and groundwater samples were grouped based on the distance of sample points. Strong, significant positive correlations were indicated when using all data. However, regression diagnostics tended to support the conclusion that distinct sets of data exist between the lower and higher concentrations. This was also indicated by the strength of the correlation being defined primarily by the sample pairs in the high concentration range. The modified conclusion presented in Section 4.2.4 is that the very high concentrations of groundwater are collocated with the higher concentrations in the soil gas (both 5 and 15 feet bgs), while those with low concentrations of groundwater are collocated with low concentrations in the soil gas. Figures 4-13 and 4-14 of the previous submittal were removed.</p>
<p><u>#5 Section 4.2.5, p. 4-11, 1st full paragraph.</u></p> <p>In the third overall paragraph of this section there is text that suggests the benzene, chlorobenzene, dichlorobenzenes, and carbon tetrachloride found on OU-1 are primarily limited to the western portion of the study</p>	<p>Section 4.2.5 of the Revised Report will be revised to clarify the relationship between benzene, chlorobenzene, dichlorobenzenes, carbon tetrachloride, and chloroform in OSSM's DNAPL plume, and how that relationship is not present in the NERT plume related to the Unit 4 building. Relevant sections from the</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, Figures 4-22a through 4-22f showing the distribution of concentrations of benzene, carbon tetrachloride, chlorobenzene, and dichlorobenzenes (1,2-, 1,3-, and 1,4-) have been added. Section 4.2.5</p>

Initial NDEP Comments (3/9/22)	NERT's First Response (6/24/22)	NDEP Comment on NERT's First Response (11/3/22)	NERT's Second Response (11/3/23)
<p>area, where the OSSM groundwater plume is located on OU-1. These analytes are said to correlate with chloroform and to also not have been used on OU-1 according to known documents. However, the report also states that chloroform was not reported to be used on OU-1, yet there is a chloroform plume related to the Unit 4 building.</p> <p>Please provide or reference figures of groundwater plumes for these chemicals to support this statement, and please provide the correlation analysis.</p>	<p>discussion presented in Section 9.4.5 of the NERT RI Report for OU-1 and OU-2 and reference to the plume figures (Figures 7-65a, 7-68a, 7-69a, 7-71a, 7-72a, and 7-73a) will be added to support the discussion. The discussion in Section 4.2.5 will also be updated with any applicable comments from NDEP on the RI Report.</p>		<p>has been revised to clarify that while there is a source of chloroform attributed to Unit 4, the elevated concentrations of benzene, chlorobenzene, dichlorobenzenes, and carbon tetrachloride found on OU-1 are considered to be primarily limited to the western portion of the study area, where the OSSM groundwater plume is located on OU-1.</p>
<p><u>#6 Executive Summary Figures ES-4 and ES-5.</u></p> <p>On Figures ES-4 and ES-5, the area around RISG-14 contains more samples at 15 ft bgs than at 5 ft bgs. Why the difference in sampling density in this location?</p>	<p>As discussed in Section 3.1.2, Phase 2 Remedial Investigation, as part of the NERT Remedial Investigation, four samples (RISG-16, RISG-17, RISG-18, and RISG-19) were located beneath the existing basement slab in the center of the Unit 4 Building. Due to depth of the basement slab, shallower soil gas samples could not be collected in these locations. A footnote can be added to the Executive Summary to emphasize this point.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, the following text, describing why no soil gas samples were collected at 5 feet bgs at specific sample locations, was added as a footnote when first reference to Figures ES-4 and ES-5 is made: "As part of the NERT Remedial Investigation, four samples (RISG-16, RISG-17, RISG- 18, and RISG-19), see Figure ES-5, were located beneath the existing basement slab in the center of the Unit 4 Building. Due to the depth of the basement slab, only soil gas samples at 15 feet bgs could be collected at these locations."</p>
<p><u>#7 Executive Summary, p. ES-6.</u></p> <p>For clarity, the closing sentence of the Executive Summary on page ES-6 should include the phrase "of the vapor intrusion pathway" before the phrase "is not warranted". This recommendation should not be construed as agreement from NDEP with the resulting phrase. The recommendation is intended to make clear to other readers that the BHRA only evaluates the vapor intrusion pathway.</p>	<p>The last sentence in the Executive Summary in the Revised Report will be modified to include "of the vapor intrusion pathway" as suggested.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, the last sentence was modified to read, "Therefore, additional assessment of the vapor intrusion pathway is not warranted based on the risk characterization results for the OU-1 Operations Area."</p>
<p><u>#8 Section 2.3, p. 2-3.</u></p> <p>The last paragraph on page 2-3 refers to narrow paleochannels. It would be helpful to update relevant figures with the location of these paleochannels relative to the soil gas and groundwater sample locations.</p>	<p>A figure showing the general geology underneath OU-1 with the location of these paleochannels can be added to Section 2 of the Revised Report. The location of these paleochannels can also be added to soil gas and groundwater sampling location figures (i.e., Figures 3-1 and 3-2) in the Revised Report.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, Figure 2-3, which specifically shows the paleochannels, was added. Paleochannel features were also added to Figures 3-1 and 3-2, which respectively show the soil gas and groundwater sample locations.</p>

Initial NDEP Comments (3/9/22)	NERT's First Response (6/24/22)	NDEP Comment on NERT's First Response (11/3/22)	NERT's Second Response (11/3/23)
<p><u>#9 Section 4.2.3.</u> Much of section 4.2 is devoted to chloroform. Yet the opening paragraph of section 5.1 states that there are 34-66 COPCs depending on matrix and depth. Additionally, table 7-4 lists chlorobenzene as a driver of HI. Please reiterate again at the beginning of section 4.2.3 why chloroform is the only analyte examined temporally.</p>	<p>As discussed in Sections 5.4.1 and 5.4.2, chloroform is the primary cancer risk and noncancer HI driver at soil gas locations and the primary cancer risk driver at groundwater locations within OU-1. Besides chloroform, no other COPC had an estimated excess lifetime cancer risk greater than 1×10^{-6}.</p> <p>Although chlorobenzene is a primary contributor to the noncancer HI at groundwater locations, all noncancer HIs were below the NDEP target HI of one, and therefore, chloroform is the only analyte examined temporally.</p> <p>Clarifying text will be added to Section 4.2.3 of the Revised Report.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>Additional text was added to Section 2.3 discussing first groundwater location and dewatering.</p> <p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, the following clarifying text was added to the beginning of Section 4.2.3, "As will be discussed in Sections 5.4.1 and 5.4.2 of this report, chloroform is the primary cancer risk driver in both soil gas and vapor migration to air from shallow groundwater. Besides chloroform, no other COPC had an estimated excess lifetime cancer risk greater than 1×10^{-6}. Chlorobenzene was the primary contributor to noncancer effects at all soil gas and groundwater locations though all calculated noncancer effects were below the NDEP and USEPA target of one. Therefore, chloroform is the only analyte examined temporally in this BHRA."</p>
<p><u>#10 Section 4.2.4.</u> Please explain why the highest area of highest concentration within the chloroform plume on the east side of OU-1 had no soil gas samples.</p>	<p>As indicated in Phase 2 RI Modification No. 9 that was approved by NDEP on June 21, 2018, there was one proposed soil gas sample (RISG-23) in this area. However, this location was on the northern berm of the Central Retention Basin and had to be relocated. Due to the ongoing treatability studies immediately adjacent to the planned location and inaccessibility from steep grades, the soil gas location proposed in the Phase 2 RI Modification No. 9 was relocated to the southwest of the proposed location. The risks from vapor intrusion were evaluated using a combination of soil gas and groundwater data. As it is the opinion of Ramboll that the groundwater concentrations in this area are well characterized, we also believe the risks are well characterized. Therefore, no changes will be made to the Revised Report.</p>	<p>Please add summary text similar to the response to this RTC to the report explaining why planned sampling within the highest area of concentration on OU-1 not related to OSSM and referencing the modification.</p>	<p>The Revised Report has been updated to reflect NDEP's clarifying comment. Specifically, the following text was added to Section 4.2.4 to describe why no samples were taken in the area with the highest groundwater impact: "As seen in Figure 3-1, no soil gas samples were obtained in the area with highest groundwater concentrations (Figure 3-2) in the Unit 4 chloroform plume. A soil gas sample (RISG-23) was originally proposed to be obtained from this area. The proposed location was on the northern berm of the Central Retention Basin within the area, showing the highest groundwater concentrations. Due to the ongoing treatability studies, immediately adjacent to the planned location, and inaccessibility from steep grades, the soil gas location proposed in the Phase 2 RI Modification No. 11 was relocated to the southwest of the proposed location."</p>
<p><u>#11 Section 4.2.4.</u> In the first line of text on page 4-10, please change 'concertation' to 'concentration'.</p>	<p>The Revised Report will be updated accordingly.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, as discussed in Comment 4, a rewrite of Section 4.2.4 was performed, and the misspelled word was not used in the new paragraph. Therefore, this comment is no longer applicable.</p>
<p><u>#12 Section 4.2.5.</u> In the fourth paragraph of this section correlations in Figures 4-13 and 4-14, it is</p>	<p>As stated in the response to Comment #4, we believe the correlation analysis plots clearly demonstrate that the correlations are driven by one or two high</p>	<p>Please see response to Comment #4. Otherwise, please provide text in section 4.2.5 that includes a discussion similar to</p>	<p>The Revised Report has been updated to reflect NDEP's clarifying comments. Specifically, as discussed in Comment 4, a rewrite of Section 4.2.4 was performed.</p>

Initial NDEP Comments (3/9/22)	NERT's First Response (6/24/22)	NDEP Comment on NERT's First Response (11/3/22)	NERT's Second Response (11/3/23)
<p>understood that the source of soil gas VOCs is likely chloroform in groundwater, and it does support the CSM, however what is shown in Figures 4-13 and 4-14 is driven largely by the two very high concentrations in the OSSM plume, representing potentially a different source than the operations area itself and representing a very small spatial area of the Operations Area. The correlations may not be representative of most of OU-1.</p> <p>Please discuss uncertainties with these correlations with respect to the entire operations area. This is discussed briefly in the first bullet point of section 4.2.4, but please reiterate some of that discussion here or at minimum provide some thoughts regarding the correlation being driven by two data points on the far western side of the Operations Area and that absent these two points the relationship between chloroform and soil gas is much more variable across the rest of OU-1.</p> <p>Note that correlation analysis is a special case of regression analysis (a simple linear regression), and regression diagnostics should be considered before presenting results of a correlation when it is clear that the apparent effect is driven by a few "influential points" or "outliers".</p>	<p>concentrations, therefore we do not believe there is a need to present regression diagnostics. Section 4.2.5 of the Revised Report can also be revised consistent with our response to Comment #4 affecting Section 4.2.4.</p>	<p>that in 4.2.4 and includes some discussion of the correlations being driven partly by samples on the western side of OU-1 that NERT may not represent chloroform derived from OU-1 operations, as planned in the above response.</p> <p>Some discussion between NDEP and NERT might be needed to resolve and fully understand this correlation issue.</p>	<p>Figures 4-13 and 4-14, previously referenced in Section 4.2.4, are no longer presented as part of the report. The discussion of these figures and the information formally located within Section 4.2.4 is no longer presented in Section 4.2.5.</p>
<p><u>#13 Table 4-5.</u> This table has several cells with "#value!" and "/FALSE". Please address accordingly.</p>	<p>Table 4.5 will be updated as required in the Revised Report.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, Table 4.5 was updated to ensure the correct information was presented in place of the "#value!" and "/FALSE" messages.</p>
<p><u>#14 Section 5.2.2.</u> Provide representative BIOVAPOR and Johnson & Ettinger modeling spreadsheets for chloroform and benzene for the various scenarios and simulated depths. In addition, the uncertainty in the BIOVAPOR and Johnson & Ettinger modeling results should be qualitatively or quantitatively discussed.</p>	<p>The Johnson & Ettinger modeling spreadsheets for all VOCs modeled and BIOVAPOR modeling spreadsheets for benzene for the various scenarios and simulated depths were included in Appendix G. Due to size of the files, these were provided electronically. Text will be added to the Table of Contents for Appendix G to clarify where these are located.</p>	<p>Response is accepted.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, within the Appendix G folder (provided electronically), both BIOVAPOR (for benzene only) and J&E files (for all evaluated chemicals) are provided. BIOVAPOR modeling files are under the 'BIOVAPOR Modeling Files' folder, with both biodegradation and non-biodegradation provided for the commercial indoor air pathway. Benzene was the only chemical for which</p>

Initial NDEP Comments (3/9/22)	NERT's First Response (6/24/22)	NDEP Comment on NERT's First Response (11/3/22)	NERT's Second Response (11/3/23)
	<p>Representative modeling spreadsheets in PDF format will also be added for chloroform and benzene.</p> <p>The uncertainty in the BIOVAPOR and Johnson & Ettinger modeling results is qualitatively discussed in Section 6, Uncertainty Analysis, under Section 6.2.2.3 Fate and Transport Modeling.</p>		<p>BIOVAPOR modeling was performed. The J&E air modeling files for each of the exposure scenarios are provided in the 'J&E Modeling Files' folder. An Excel workbook is provided for each exposure scenario and contains multi-chemical evaluations.</p> <p>For convenience, the Excel workbook 'Summary Benzene Transfer Factors.xlsx' is provided which summarizes the estimated transfer factors for Benzene in one table.</p>
<p><u>#15 Figure 5-5.</u></p> <p>The transfer factors in Table 5-5 are more than 10 orders-of-magnitude less than those for the other COPCs and suggest that benzene will not be detected in indoor air under any circumstances. The low transfer factors for benzene are likely the result of the modeled degradation rates. It has been our experience that benzene is routinely detected in outdoor air (and indoor air) in most (if not all) urban/suburban areas suggesting that the modeled degradation rates may be incorrect or there are other sources (e.g., automobiles and trucks). Please comment in the Uncertainty Analysis.</p>	<p>It should be noted that the BIOVAPOR and Johnson & Ettinger models predict vapor migration from the subsurface to indoor air. The models do not take into account either the impact of existing indoor or ambient sources on indoor air concentrations.</p> <p>The Uncertainty Analysis section of the Revised Report will be expanded to include discussion of other sources of benzene in the ambient environment.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, language has been added to indicate that the BIOVAPOR and J&E models do not take into account either the impact of existing indoor or ambient sources. To specifically address NDEP's concern regarding benzene, other potential sources of benzene in the indoor environment are discussed in the final paragraph of Section 6.2.2.2 of the Uncertainty Section.</p>
<p><u>#16 Figure 3-1.</u></p> <p>This includes all spatial plots, but there is a noticeable 'pinch' of the plume around wells MW-16, M-5A, RISG-80, and other locations in this area. This did not seem to be highlighted in the text.</p> <p>Please provide an interpretation or description of the underlying mechanism by which the OSSM plume is essentially 'splitting'.</p>	<p>The divergence of the OSSM plume in this area is likely caused by the presence of a topographic high of the less permeable Upper Muddy Creek Formation near and north of M-5A, MW-16(NERT), and RISG-80. This topographic high is illustrated on Figure 5-8 (Subsurface Cross-Section F-F') in the RI Report for OU-1 and OU-2. The text will be revised to incorporate additional discussion of the spatial distribution of the chloroform plume in this area.</p> <p>In addition, per the response to Comment 9 above, a figure showing the general geology underneath OU-1 with the location of the paleochannels will be added to Section 2 of the report. The locations of these paleochannels will also be added to the soil gas and groundwater sampling location figures (i.e., Figures 3-1 and 3-2).</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, Figure 2-3 which specifically shows the paleochannels was added. Paleochannel features were also added to Figures 3-1 and 3-2 which respectively show the soil gas and groundwater sample locations.</p> <p>The following text describing reasons for this potential divergence was added to Section 4.2.2: "As shown on Figure 3-2, the OSSM plume bifurcates into two lobes in the northwest corner of OU-1. This bifurcation was caused by the presence of a topographic high of the less permeable Upper Muddy Creek Formation (UMCf) beginning near wells M5A and MW-16 (NERT) and extending to the north near wells M-6A, M-7B, M-205, and M-206. This UMCf high is illustrated on the cross-section along the southern boundary of Former Parcels C & D in Figure 3-3 (Subsurface Cross-Section F-F'). As shown on the cross-section, the UMCf high extends from approximately well M-6A to well M-206. The</p>

Initial NDEP Comments (3/9/22)	NERT's First Response (6/24/22)	NDEP Comment on NERT's First Response (11/3/22)	NERT's Second Response (11/3/23)
			<p>bifurcation of the OSSM plume would have occurred prior to the startup of the IWF in 1987 when groundwater levels were higher within OU-1. Under the current conditions shown on the cross-section, the groundwater level within OU-1 is generally below the contact between the alluvium and the UMCf. However, the groundwater levels measured in 1985 were approximately 20 ft higher in the central portion of OU-1 along the line of the cross-section causing the higher permeability alluvium to be saturated to the east of the UMCf high (Ramboll 2023b). Under these historical higher water levels, the OSSM plume bifurcated into the two lobes observed on the chloroform plume map as the groundwater flow followed the preferential pathways represented by saturated alluvium to the west and east of the UMCf high."</p>
<p><u>#17 Section 5.1.</u> This document attributes 6 COPCs entirely to the OSSM plume and references the Ramboll 2021a document for this, however that document is still under review. Please provide a brief explanation of why all of these are being attributed solely to the OSSM plume in this report.</p>	<p>Section 5.1 of the Revised Report will be modified to present a standalone justification for the referenced conclusion.</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, this comment was addressed in Comment 5. A reference to Section 4.2.5 is presented at the end of Section 5.1 indicating the six COPCs are discussed in Section 4.2.5.</p>
<p><u>#18 Table E-1.</u> The OU-1 Groundwater BHRA Data Set has a result of 0.000005 µg/L for formaldehyde in sample M-249-60-20171113 while the BMI has a result of 5 µg/L (converted from 0.005 mg/L in the EDD). Please check on this sample and verify the result reported in Table E-1.</p>	<p>Table E-1 of the Revised Report will be corrected as required. This impacts two formaldehyde samples, M-249-60-20171113 and M-251-60- 20171114. The impact on the total risk results at these two groundwater sample locations is negligible due the low detected levels of formaldehyde (5 µg/L compared to the indoor worker RBTC of 300,000 µg/L for formaldehyde).</p>	<p>Response is accepted, pending review of the revised report.</p>	<p>The Revised Report has been updated to reflect NDEP's acceptance of NERT's June 24, 2022 response. Specifically, formaldehyde results in Table E-1 were updated to correct the conversion error present in the original report. As indicated in the response to the initial comment, this conversion issue had no impact on the overall results of the evaluation.</p>
